[AMA quick guide to telemedicine in practice](#)

The use of telemedicine and remote care services are critical to the safe management of the COVID-19 pandemic, while also ensuring uninterrupted care for 100 million Americans with chronic conditions. Telemedicine spans a continuum of technologies that offer new ways to deliver care including:

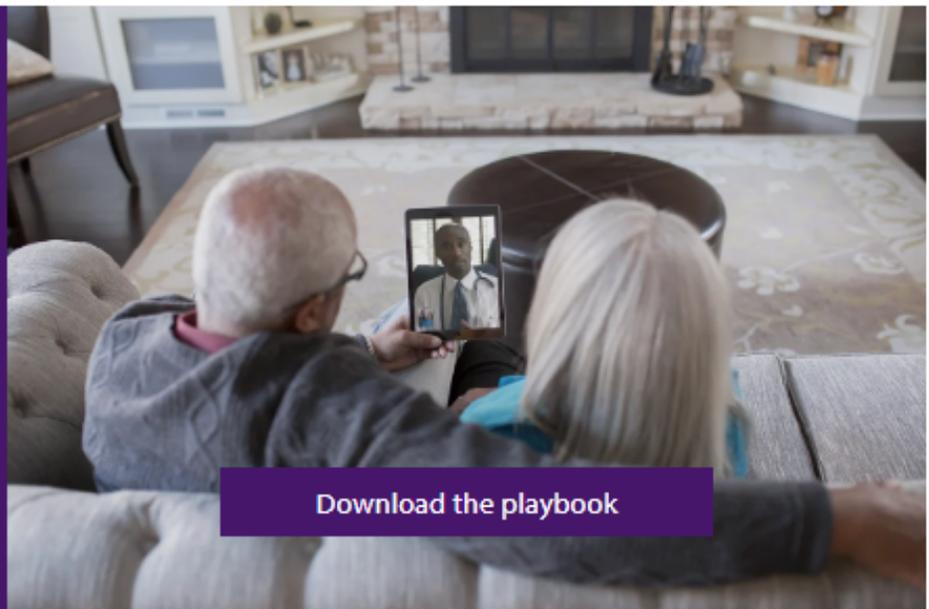

- Real-time, audio-video communication tools (telehealth) that connect physicians and patients in different locations.
- Store-and-forward technologies that collect images and data to be transmitted and interpreted later.
- Remote patient-monitoring tools such as blood pressure monitors, Bluetooth-enabled digital scales and other wearable devices that can communicate biometric data for review (which may involve the use of mHealth apps).
- Verbal/Audio-only and virtual check-ins via patient portals, messaging technologies, etc.

The AMA Digital Health Implementation Playbook series offers comprehensive step-by-step guides to implementing digital health solutions, specifically telemedicine, in practice based on insights from across the medical community. Each Playbook offers key steps, best practices and resources to support an efficient and clear path to implementation and scale.

Our newest Playbook in the series focuses on [the implementation of telehealth](#) (PDF), defined as real-time, audio-visual visits between a clinician and patient. We have also created this quick guide for key implementation tips and the latest updates on telemedicine expansion amid COVID-19.

Telehealth Implementation Playbook

Critical integration of new digital tools in medicine is lacking. We want to change that.
